Computer Simulation of ALICE Project for the Detection of the Resonance Kaon

Coli Simone

November 24th, 2021

1 Abstract

ALICE_Simulation is a computer program that simulates the ALICE experiment that has been conducted at CERN since 1993, which consists of analyzing the collisions occurring between particles at very high energies(1). Those particles would create different particles following a probability distribution (Table1).

Particle Type	Probability
π^+	40%
π^-	40%
k^+	5.0%
k^-	5.0%
P^+	4.5%
P^-	4.5%
k^*	1.0%

Table 1: *The table shows the probability of obtaining a specific particle from a collision of high energy particles*

In the simulation, we generated a finite amount of particles from the collision of the flux in the particle accelerator, each with a proper momentum, mass, and resulting energy, to maintain the conservation of those properties.The goal of the experiment is to detect the existence of Kaon 0 (k^*), a very rare particle that decays into either a Positive Pion (π^+) and Negative Kaon (k^-) or a Negative Pion (π^-) and Positive Kaon (k^+), after only $5.2 \times 10^{-8}s$. We stored the data of momentum, energy, charge, and invariant mass of all the particles to detect the presence of differences that could indicate the existence of the Kaon.

The program we implemented stores the information about the particles and generates histograms from which we studied the system.

2 Code Structure

The code's division into different files and folders has the background idea of making it more orderly. There are eight files for the simulation program (one main file: `mainE.cpp`, one libraries file: `library.hpp`, three header files: `ParticleType.hpp`, `ResonanceType.hpp`, `Particle.hpp`, and three source files: `ParticleType.cpp`, `ResonanceType.cpp`, `Particle.cpp`) and one for the data analysis (`analysis.C`). The header files contain the classes implemented for the proper functioning of the simulation, whereas the source files contain the implementation of the methods defined in the headers.

ParticleType Class

The class `ParticleType` creates a homonymous type that contains the name, the mass, and the charge of a particular particle, respectively as a `std::string`, a `double`, and an `integer`. This class has five methods, two of which are virtual.

ResonanceType Class

The `ResonanceType` class is a derived class from `ParticleType` and, in addition to the base class items, contains the information about the width of the particle as a `double`. The type defined with the name of this class creates a particle with a width, contrary to what happens to a `ParticleType` object, in which the width of the particle is always zero. This class has two methods, both of them are the override of the already existing virtual methods in the base class.

Particle Class

The class `Particle` is the one that allows the creation of a particle giving it a random momentum and making it decay into other particles if necessary. It also creates a set of particle type, each with a proper index as an identifier. The variables in this class are three momentum components (`fPx`, `fPy`, `fPz`), an array of ParticleType and its dimension (`fParticleType`, `fMaxNumParticleType`), an index of particle type (`fNParticleType`), and a numeric code proper of each particle type (`fIndex`). This class has several methods including some static, meaning they are accessible from the main without defining an object.

3 Generation

In the simulation, there had been 100000 collision events, each using a set of 100 particles. The particles resulting from the collisions were Positive Pions (π^+), Negative Pions (π^-), Positive Kaons (k^+), Negative Kaons (k^-), Protons (p^+), Antiprotons (p^-), and Resonance Kaons (k^*), generated randomly using a uniform distribution and the probability shown in Table 1. The module of the momentum of the particles comes from an exponential distribution with a mean of 1. Its direction drives from the cartesian components:

$$\begin{cases} p_x = |\vec{p}\,| \cdot \cos\theta \cdot \cos\phi \\ p_y = |\vec{p}\,| \cdot \cos\theta \cdot \sin\phi \\ p_z = |\vec{p}\,| \cdot \sin\theta \end{cases} \tag{1}$$

Where the azimuthal angle theta (θ) and the polar angle phi (ϕ) are generated using a uniform random distribution respectively from 0 to π and the second from 0 to 2π. In the case that a Resonance Kaon is created from the collision of particles, it deacys into either a Positive Pion and a Negative Kaon or a Negative Pion and a Positive Kaon with the same probability. The momentum of these new two particles comes from a normal distribution.

4 Analysis

The generation of particle types is compatible with the theoretical calculation as shown in Table. 2

Particle Type	Entries	Error	Theo. Ent.
π^+	4000250	2000	$4.0 \cdot 10^6$
π^-	3998440	2000	$4.0 \cdot 10^6$
k^+	500727	707	$5.0 \cdot 10^5$
k^-	499365	707	$5.0 \cdot 10^5$
P^+	450417	671	$4.5 \cdot 10^5$
P^-	450536	671	$4.5 \cdot 10^5$
k^*	100264	317	$1.0 \cdot 10^5$

Table 2: *The table shows the entries from the simulation with the respective error obtained using the specific ROOT method, and the theoretical entries calculated taking the percentage of each particle type from the total amount of particles.*

The angles and momentum distributions are fitting to the relative uniform and exponential distribution as shown in table 3.

Distribution	Fit's Parameters	χ^2	D.O.F.	Reduced χ^2
Polar Angles (pol0)	9999 ± 3	973.8	999	0.9748
Azimutal Angols (pol0)	9999 ± 3	902.8	999	0.9037
Momentum (expo)	$(9939 \pm 3) \cdot 10^{-4}$	959.2	998	0.9961

Table 3: *The table shows the results of the fits from the histograms of the angles and the momentum.*

It is possible to analyze these phenomena by looking at the histograms of the invariant mass, because its definition contains both the momentum and the energy of the particles and it is, therefore, conserved in the collision. The construction of the invariant mass histogram consist of counting the number of particles per mass invariant value and to detect the resonance Kaon. We considered the histogram only for Pion and Kaon with different charges and we compared it with the histogram of the Pion and Kaon with the same charges. Because the resonance Kaon decays very quickly into those two particles with opposite charges, there should be a little "bump" in the first of those two histograms. A second approach consists of comparing the two histograms of the invariant mass of all the particles with the same charge and opposite charges.
Subtracting the two pairs of histograms gives, in both cases, a bell shape, fitting a normal distribution with mean being the mass of the resonance Kaon and sigma its width, as shown in the histograms Differenza 1 and Differenza 2 in Fig. 2. To chack the results of the simulation and the analysis we compared the mean and the width obtained from those fits with the parameters of the fit from the histogram of the invarian mass of the decay, in Fig. 2.

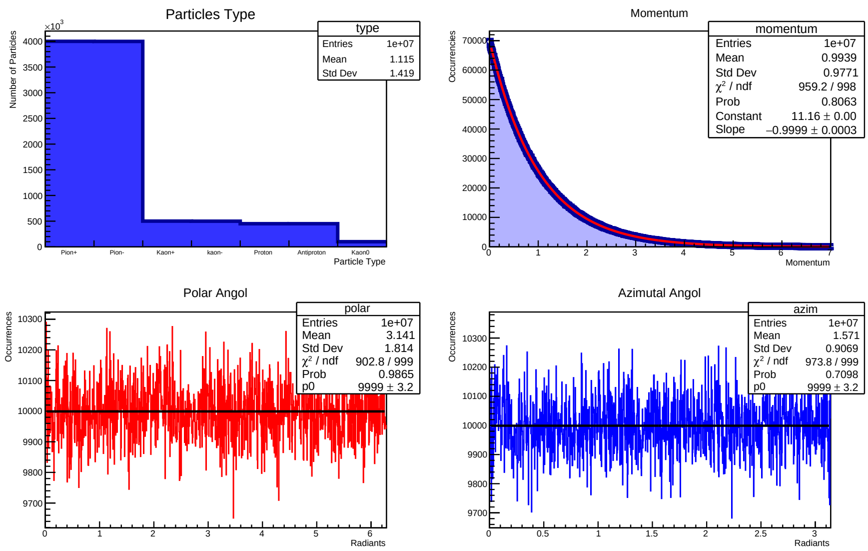

Figure 1: *The image shows the fit between the uniform distribution compared with the histograms of the angles randomly generated and the histogram of the momentum with the exponential distribution.*

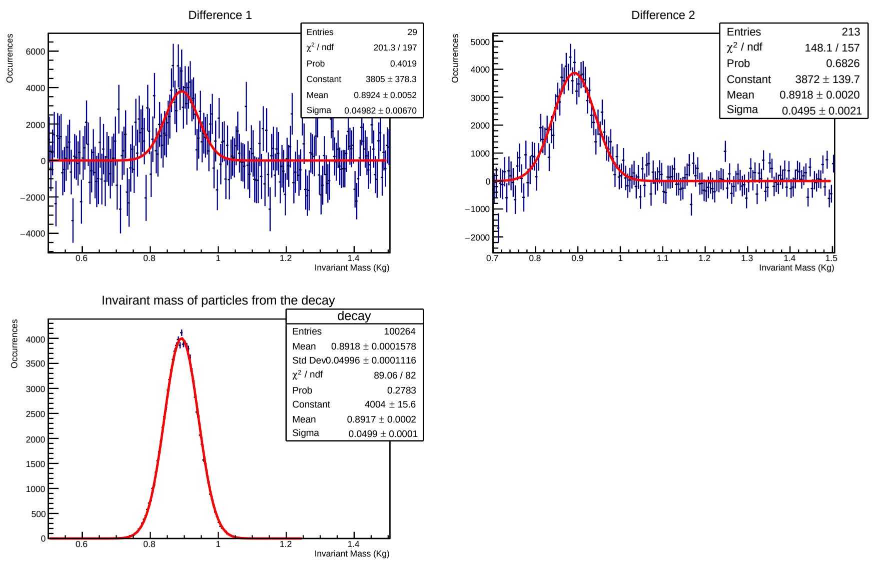

Figure 2: *The image shows the histograms of the invariant mass calculated in the three different ways: Differenza 1 is the result of subtracting the histogram of the invariant mass of the particles with opposite charges with the one with particles of the same charge; Differenza 2 derives from the subtraction of the histogram of the invariant mass of Pions and Kaons with different charges and one of Pions and Kaons with the same charge; Invariant mass of particles from the decay is the histogram of the invariant mass of the resulting particles from the decay of the Kaon*. All of them fitted using a normal distribution.*

In conclusion, from the previous considerations, we had been able to detect the presence of a resonance Kaon and the result of the simulated experiment has been summarized in table 4.

Distribution	Mean	Sigma	Amplitude	χ^2
Inv. Mass. Decay	0.8917 ± 0.0002	4004 ± 15	999	1.086
Inv. Mass. Charges	0.8924 ± 0.0052	3805 ± 378	999	1.021
Inv. Mass. Kaon-Pion	0.8918 ± 0.0020	3872 ± 140	998	0.9433

Table 4: *The table summarize the result of the fit of all the histograms of the invariant mass.*
